CS 31 Worksheet 4 Solutions

This worksheet is entirely **optional**, and meant for extra practice. Some problems will be more challenging than others and are designed to have you apply your knowledge beyond the examples presented in lecture, discussion or projects. All exams will be done on paper, so it is in your best interest to practice these problems by hand and not rely on a compiler.

Concepts

Functions, Parameter Passing Arrays

1. Show what will be printed by each of the following programs.

```
#include <iostream.h>
void doglobal();
void dolocal();
void doref(int&);
void doval(int);
int x;
int main()
  x = 15;
   doref(x);
   cout << "x = " << x << " after the call to dorefn";
   x = 16;
   doval(x);
   cout << "x = " << x << " after the call to doval\n";
   x = 17;
   dolocal();
   cout << "x = " << x << " after the call to dolocal\n";
   x = 18;
   doglobal();
   cout << "x = " << x << " after the call to doglobal\n";
   return 0;
void doref(int& a)
   a = 3;
void doval(int b)
   b = 4;
void dolocal()
   int x;
```

```
x = 5;
    void doglobal()
       x = 7;
    x = 3 after the call to doref
a.
      x = 16 after the call to doval
      x = 17 after the call to dolocal
      x = 7 after the call to doglobal
b. #include <iostream.h>
    int num = 10;
    void one();
    void two(int);
    void three();
    void four(int&);
    void five(int&);
    int main()
       int num = 1;
       cout << "At start of main num = " << num << endl;</pre>
       cout << "After call to one num = " << num << endl;</pre>
       two (num);
       cout << "After call to two num = " << num << endl;</pre>
       cout << "After call to three num = " << num << endl;</pre>
       four (num);
       cout << "After call to four num = " << num << endl;</pre>
       two(num);
       cout << "After call to two num = " << num << endl;</pre>
       one();
       cout << "After call to one num = " << num << endl;</pre>
       five (num);
       cout << "After call to five num = " << num << endl;</pre>
       cout << "After call to one num " << num << endl;</pre>
    void one()
       cout << "
                   At the start of one num = " << num << endl;
       num = 50;
                    At the end of one num = " << num << endl;
       cout << "
    void two(int num)
       cout << "
                    At the start of two num = " << num << endl;
       num = 5;
       cout << " At the end of two num = " << num << endl;</pre>
```

```
void three()
       int num = 100;
       cout << " At the start of three num = " << num << endl;</pre>
       num = 200;
       cout << " At the end of three num = " << num << endl;</pre>
    void four(int& num)
                   At the start of four num = " << num << endl;
       cout << "
       num = 25;
       cout << "
                   At the end of four num = " << num << endl;
    }
    void five(int& i)
       cout << " At the start of five num = " << num << endl;</pre>
       num = 2;
       i = 3;
       cout << "
                 At the end of five num = " << num << endl;
      At the start of main num = 1
b.
         At the start of one num = 10
         At the end of one num = 50
      After call to one num = 1
         At the start of two num = 1
         At the end of two num = 5
      After call to two num = 1
         At the start of three num = 100
         At the end of three num = 200
      After call to three num = 1
         At the start of four num = 1
         At the end of four num = 25
      After call to four num = 25
         At the start of two num = 25
         At the end of two num = 5
      After call to two num = 25
         At the start of one num = 50
         At the end of one num = 50
      After call to one num = 25
         At the start of five num = 50
         At the end of five num = 2
      After call to five num = 3
         At the start of one num = 2
         At the end of one num = 50
      After call to one num = 3
c. #include <iostream.h>
```

void triple(int);

```
int main(void)
       int x;
       for (x = 1; x \le 5; x++)
          triple(x);
    }
    void triple(int value)
       static int total = 0;
       int answer;
       answer = 3 * value;
       total += answer;
       cout << value << ' ' << answer << endl;</pre>
       cout << "total " << total</pre>
             << endl << endl;
    }
c. 1 3
    total 3
    2 6
    total 9
    3 9
    total 18
    4 12
    total 30
    5 15
    total 45
```

2. Declare a function named scan that reviews an array of int and returns the largest and smallest number found in the array. HINT #1: You'll need to pass an array argument and a companion size parameter. HINT #2: Since you are returning more than one value from your function, you'll need to use reference parameters. Implement this function and then write statements to call this function with an array of size 5.

```
2. void scan(int array[], int size, int& largest, int& smallest);
  void scan(int array[], int size, int& largest, int& smallest);
  {
    if (size > 0)
    {
        largest = array[ 0 ];  // to start with...
        smallest = array[ 0 ];
    }
    for (int i = 0; i < size; i++)</pre>
```

```
{
    int value = array[ i ];
    if (value > max)
        max = value;
    if (value < min)
        min = value;
}

int main()

{
    int values[ 5 ] = { 1, 2, 3, 4, 5 };
    Int big, small;
    scan( values, 5, big, small );
    return( 0 );
}</pre>
```

3. What is the output of the following program?

```
#include <iostream.h>
   int main()
    {
      int a[100], b[100], j, m;
      int suma = 0, sumb = 0, sumdiff = 0;
      cin >> m;
      for (j = 0 ; j < m ; j++)
         cin >> a[j] >> b[j];
         suma = suma + a[j];
         sumb += b[j];
         sumdiff = sumdiff + (a[j] - b[j]);
      for (j = m - 1 ; j >= 0 ; j--)
         cout << a[j] << " " << b[j] << " " << a[j] - b[j] << endl;</pre>
      cout << suma << " " << sumb << " " << sumdiff << endl;
    }
   DATA:
   11 15
   19 14
   4 2
   17 6
   1 3
3. 1 3
           -2
          11
   17 6
   4
       2
           2
   19 14 5
   11
       15 -4
   52 40 12
```

```
4. Given: int h = 6, p = 2, m = 3;
    int values[7];
Suppose values contains: -4 0 2 6 -2 -1 14
Show the contents of the array values after:
    for (; m <=5; m++)
        values[m] = values[h] + values[p] * values[m];</pre>
```

4. -4 0 2 26 10 12 14

5. Given the declarations:

```
int sample[8], i, k;
```

show the contents of the array sample after the following code is executed. Use a question mark to indicate any garbage values in the array.

```
for (k = 0 ; k < 8 ; k++)
if (k % 2)
sample[k] = 1;
```

- 5. subscript [0] [1] [2] [3] [4] [5] [6] [7] value ? 1 ? 1 ? 1 ? 1
- 6. What is the error in the following program segment?

```
int main()
{
   int i, count[10];
   cout << "please enter 10 numbers: ";
   for (i = 1; i <= 10; i++)
       cin >> count[i];
}
```

- 6. This is a logical error. It will not result in an error message from the compiler, but may result in a run time error. The array has subscripts that run from 0 through 9, but the loop reads into array locations 1 through 10. Storing a value into count[10] will either overwrite another variable or some code in this program, or will access memory allocated to a different program, which will cause this program to terminate execution.
- 7. Write the statements to multiply every element of an array of ints (of size 50) by 2.

```
7. for (i = 0 ; i < 50 ; i++)
nums[i] = nums[i] * 2;
```

8. Write the statements to add up those elements of an array of ints (of size 25) which have an even subscript.

```
8. for (sum = 0, i = 0; i < 25; i = i + 2)

sum = sum + nums[i];
```

9. Write the statements to add up those elements of an array of ints (of size 25) which have an even value.

```
9. for (sum = 0, i = 0; i < 25; i++)
    if (nums[i] % 2 == 0)
    sum = sum + nums[i];</pre>
```

10. What will the following program segment print?

```
int main()
      int nums[10];
      int i;
      for (i = 9 ; i >= 0 ; i--)
         nums[i] = 5 * (i + 1);
         cout << nums[i] << " ";
      cout << endl;</pre>
      for (i = 0 ; i < 9 ; i++)
         cout << nums[i] << " ";
      cout << endl;</pre>
      for (i = 0 ; i < 9 ; i++)
         nums[i+1] = nums[i];
      for (i = 0 ; i < 9 ; i++)
         cout << nums[i] << " ";
      cout << endl;
    }
10.50 45 40 35 30 25 20 15 10 5
   5 10 15 20 25 30 35 40 45 50
      5 5 5 5 5 5
```

11. What will the following program segment print?

```
int main()
{
   int nums[10];
   int i;
   for (i = 9; i >= 0; i--)
   {
      nums[i] = 5 * (i + 1);
      cout << nums[i] << " ";
}</pre>
```

```
cout << endl;</pre>
       for (i = 0 ; i < 9 ; i++)
           cout << nums[i] << " ";</pre>
       cout << endl;</pre>
       for (i = 8 ; i >= 0 ; i--)
           nums[i+1] = nums[i];
       for (i = 0 ; i < 9 ; i++)
           cout << nums[i] << " ";
       cout << endl;</pre>
    }
11. 50 45 40 35 30 25 20 15 10 5
    5 10 15 20 25 30 35 40 45 50
    5 5 10 15 20 25 30 35 40 45
12. Given:
          int temps[50];
 Write the statements to print "yes" if any element of the array
 temps contains the value 100.
 Here are two different possible solutions for this problem.
    found = 0;
    for (i = 0 ; i < 50 \&\& found == 0; i++)
       if (temps[i] == 100)
           cout << "yes\n";</pre>
           found = 1;
    here the for loop doesn't have a body; the loop will exit if it
    gets to the end of the array, or if it finds an array element
    which contains 100. after the loop, we need to know which of the
    two conditions caused the loop to exit. if i == 50, that means
    that we got all the way through the loop and never found 100;
    otherwise, atleast one element contained 100
    for (i = 0 ; i < 50 \&\& temps[i] != 100 ; i++) ;
    if (i < 50)
       cout << "yes\n";</pre>
13. Given:
          int temps[50];
 Write the statements to set the variable found to true if any
 element of the array temps contains the value 100. If not, the
```

```
bool found = false;
for (i = 0 ; i < 100; i++)
{
   if (temps[i] == 100)</pre>
```

variable found should be false.

```
{
    found = true;
    break;
}
```
